

The Genetics of Usher Syndrome

Heidi L. Rehm, PhD, FACMG

Assistant Professor of Pathology, Harvard Medical School

Director, Laboratory for Molecular Medicine, PCPGM

We inherit two copies of each chromosome (and each gene), one from each parent.

Autosomal Recessive Inheritance

For Usher syndrome, both copies of a gene must be mutated to get the disease.

Often, there is no family history of Usher syndrome.

Each child will have a 25% chance of getting Usher.

A carrier is a person who has one copy of a recessive mutation, but is not affected.

Inheritance Patterns Observed with Usher and RP

Usher syndrome is recessive

Retinitis pigmentosa can be recessive, dominant, X-linked or mitochondrial

What is it?

Determine whether you have a variant in a gene which can result in a disease

What can be tested?

Metabolic substances (newborn screening – e.g. PKU)

Proteins (IRT for CF screening)

Chromosomes (Down's Syndrome)

DNA (Connexin 26)

Chromosome Abnormalities

Trisomy 21 (Down's Syndrome)

DNA Testing

Usher genetic testing must be done by DNA analysis.

Normal Sequence

ATG GTG CCT CAG GAT

Mutated Sequence

ATG GTG CCT TAG GAT

Usher Syndrome Early Diagnosis

ERG and other ophthalmological exams – may not be positive initially. Often requires sedation for infants and very young children.

Vestibular assessment (delayed motor milestones, VEMP, minimized rotation testing, caloric, rotary chair) – test methods are age dependent and not diagnostic for USH1 (not useful for USH2)

- Teschner 2007: 16.2% of deaf children had absent vestibular responses from a new “minimized rotation” test and 50% of them had abnormal ERGs

Genetic testing: Can be performed at any age with a blood sample. May not find the cause.

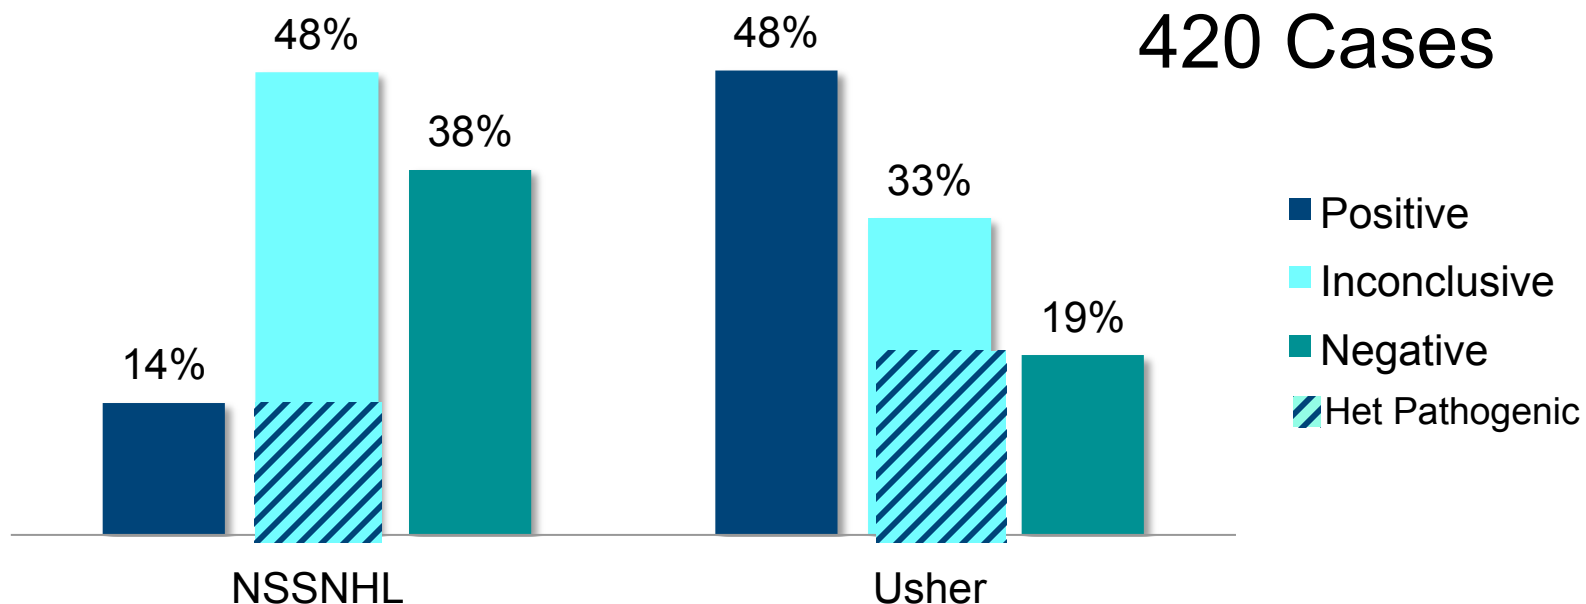

Usher Type	Locus	Gene	Relative Incidence*
USH1A	Retracted (6/9 families have MYO7A mutations)		
USH1B	11q13.5	<i>MYO7A</i>	39-55%
USH1C	11p15.1	<i>USH1C</i>	6-7%
USH1D	10q	<i>CDH23</i>	19-35%
USH1E	21q	unknown	Rare
USH1F	10q21.1	<i>PCDH15</i>	10-20%
USH1G	17q24-25	<i>SANS</i>	7%
USH2A	1q41	<i>USH2A</i>	80%
USH2B	Retracted		
USH2C	5q14.3-q21.3	<i>VLGR1</i>	15%
USH2D	9q32	<i>WHRN</i>	5%
USH3	3q21-q25	<i>USH3</i>	100%

*Relative incidences from Usher I/II GeneReviews

Causes of Childhood Hearing Loss

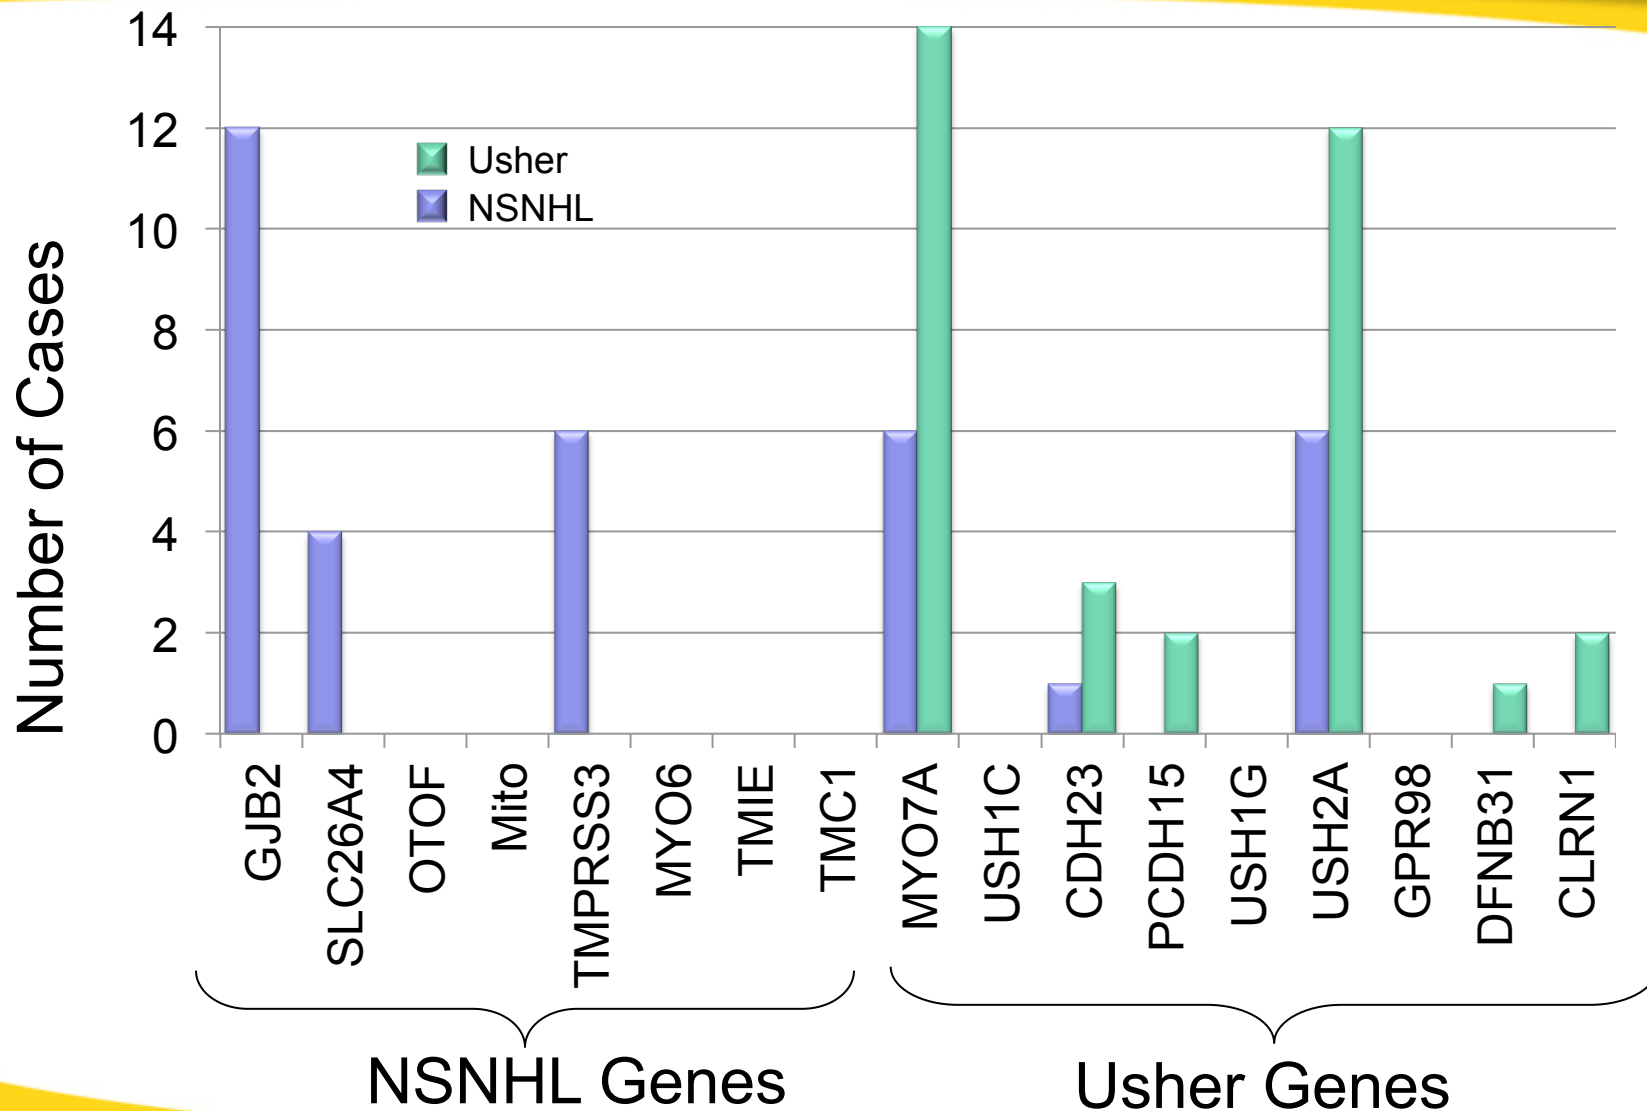

OtoChip Results – 19 Genes for HL and Usher

The OtoChip detected a clear or likely etiology in 28% of hearing loss cases and 68% of possible Usher syndrome cases.

23/241 (9%) of early childhood (≤ 10 yr) HL cases tested positive for an Usher gene mutation

OtoGenome Test for Hearing Loss

We are pleased to announce the launch of the new **OtoGenome Test™** for hearing loss and related syndromes, performed using next-generation sequencing. The comprehensive approach of the OtoGenome Test™ now makes it possible to sequence 71 genes known to cause nonsyndromic hearing loss and syndromes that can present as nonsyndromic such as Usher, Pendred, Jervell and Lange-Nielsen (JLNS), and Branchio-Oto-Renal syndrome (BOR).

For a lower cost, patients can also order the **Usher Syndrome Panel** examining only the 10 genes associated with Usher syndrome. This test panel is recommended for individuals with a clinical diagnosis of Usher syndrome. If this test is negative patients can reflex to the remaining 61 genes of the OtoGenome Test for a discounted price.

OtoGenome Test™: ACTG1, ATP6V1B1, BSND, CCDC50, CDH23, CLDN14, CLRN1, COCH, COL11A2, CRYM, DFNA5, DFNB31, DFNB59, DIAPH1, ESPN, ESRRB, EYA1, EYA4, GIPC3, GJB2, GJB3, GJB6, GPR98, GPSM2, GRHL2, GRXCR1, HGF, ILDR1, KCNE1, KCNQ1, KCNQ4, LHFPL5, LOXHD1, LRTOMT, MARVELD2, MIR183, MIR96, MSRB3, MTRNR1 (12S rRNA), MTTT1 (tRNA^{Ser}(UCN)), MYH14, MYH9, MYO15A, MYO1A, MYO3A, MYO6, MYO7A, OTOA, OTOF, PCDH15, PDZD7, POU3F4, POU4F3, PRPS1, RDX, SERPINB6, SLC17A8, SLC26A4 (PDS), SLC26A5, TECTA, TIMM8A, TJP2, TMC1, TMIE, TMPRSS3, TPRN, TRIOBP, USH1C, USH1G, USH2A, WFS1

Usher Syndrome Panel: CDH23, CLRN1, DFNB31, GPR98, MYO7A, PCDH15, PDZD7, USH1C, USH1G, USH2A

Test Pricing

OtoGenome Test for Hearing Loss (71 genes)	\$3600
Usher Syndrome Panel (10 genes)	\$2500
Reflex from Usher Syndrome Panel to full OtoGenome Test	\$1800

Turn-Around-Time: 8-12 weeks

Why does genetic testing take so long?

The Usher Gene Panel covers 9 genes broken into 208 pieces (exons) and spanning 44,607 bases of DNA sequencing.

The test is first run using a technology called next generation sequencing. Then we fill in the missing holes and confirm all of the variants we find using a higher quality technology called Sanger sequencing.

Then we interpret all of the DNA variants we find (typically 50-100 per patient).

Failed Regions (7 entries, 9 amplicons)

FILTER OUT

- No Sanger
- No further variant assessment
- Not included on patient report

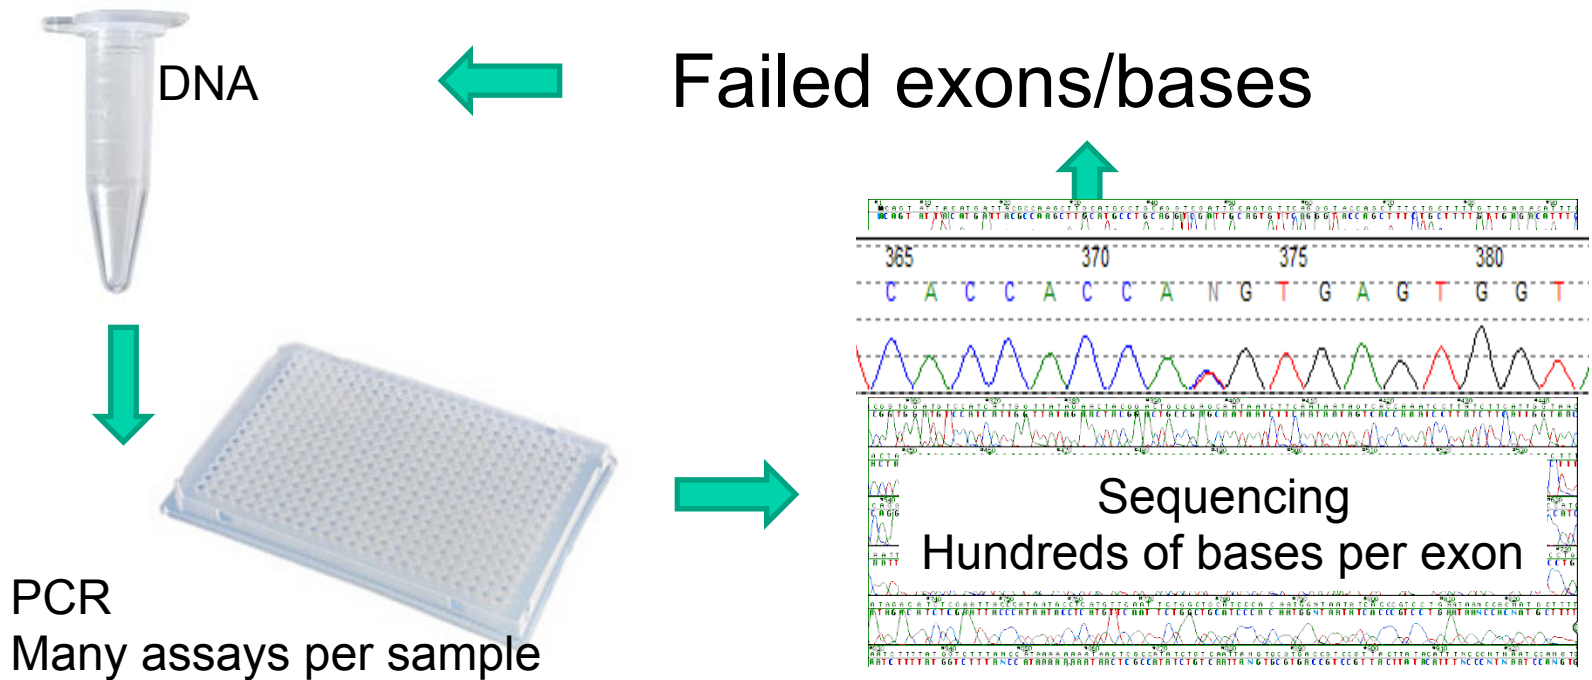

Sanger Sequencing Follow-Up for OtoGenome

Average Follow-up: 27 amplicons (out of 1439)

A Genetic Sequencing Test is Not One Test

One Usher Test is actually 44,607 tests with an infinite number of possible results. After the NGS process, Sanger follow-up begins:

Sanger Sequencing Follow-up

Good Sequence with Mutation

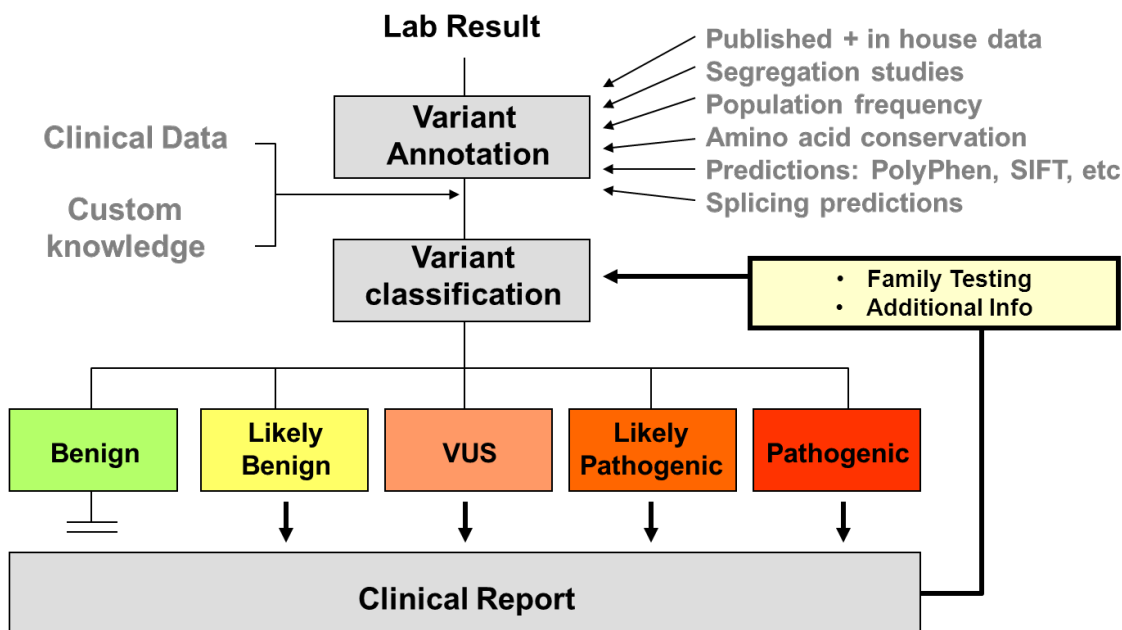

Failed Sequence

Each round of Sanger sequencing takes ~ 1 week
Any failed sequence must be repeated. We often repeat certain exons up to 6-8 times before success

Variant Assessment and Reporting

Variant Assessment Type	Average
Variant with no data	22 min
Variant with dbSNP/ESP data only	25 min
Variant with publications	120 min

~15,000 variants interpreted in patient reports to date

We typically find 50-100 variants per patient in an Usher test.

Hearing Loss Gene Mutations – 2000 Cases Tested

Usher Common Mutation Testing Panel

Dx	Allele 1	Allele 2

Usher Syndrome

	Hearing Loss	Vestibular System	Retinitis Pigmentosa
Type I	Congenital profound	Congenital balance problems	Onset pre-puberty
Type II	Congenital mild-severe sloping	Normal	Onset in teens-20s
Type III	Progressive later onset	Progressive balance problems	Variable onset

Hearing Loss Severity with USH1 Gene Mutations

■ Usher 3 yr - 48 yr

■ NSNHL 4 mo - 5 yr

Mutations in Usher Type 1 genes may not cause an Usher Type 1 phenotype

Nonsyndromic Hearing Loss or RP due to Usher Gene Mutations

Usher Type	Gene	Nonsyndromic Form
USH1B	<i>MYO7A</i>	DFNA11, DFNB2 (rare)
USH1C	<i>USH1C</i>	DFNB18 (mutations in a certain region of gene)
USH1D	<i>CDH23</i>	DFNB12 (mild mutations)
USH1F	<i>PCDH15</i>	DFNB23 (mild mutations)
USH1G	<i>USH1G (SANS)</i>	Not reported
USH2A	<i>USH2A</i>	Autosomal recessive RP (12% of arRP)
USH2C	<i>VLGR1</i>	Not reported
USH2D	<i>DFNB31 (WHRN)</i>	DFNB31 (short isoform mutations)
USH3A	<i>CLRN1</i>	Not reported

Why are there different clinical presentations for certain genes?

Some variants are milder than others.

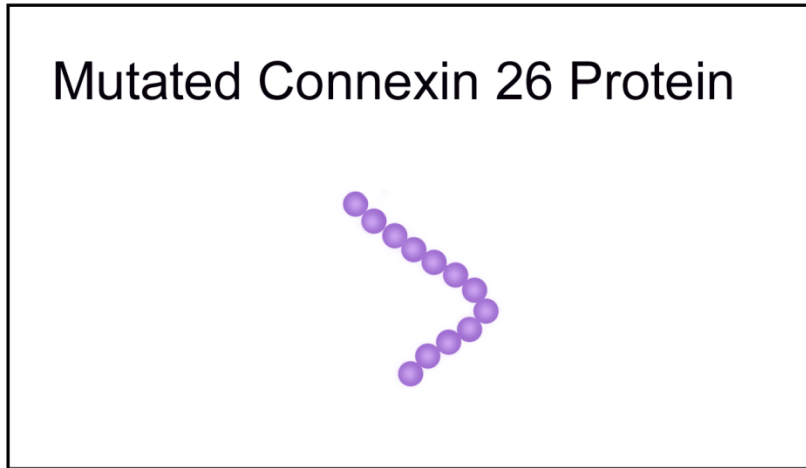

Some variants lead to full loss of the protein (e.g. full or partial gene deletions, nonsense, frameshift and splice variants as well as some missense variants (due to protein misfolding or mislocalization)).

Other variants may leave the protein intact but modify it slightly (e.g. certain missense variants) – it is these variants that lead to some nonsyndromic presentations with Usher syndrome gene variants.

In some cases (USH1C) different parts of the gene create different proteins in eye versus ear only cause hearing loss

Sometimes clinical presentation is affected by modifiers. Modifiers can be genetic (variants in other genes) or environmental (exposures, lifestyle, etc).

Truncating Mutations such as Nonsense, Frameshift, Splicing and Large deletions Usually Lead to Complete Loss of a Protein

Normal Connexin 26 Protein

Missense Mutations Change Only One Amino Acid

Whole Exome and Genome Sequencing

Sequencing the genome could increase disease detection rates to 100%.

Sequencing costs are dropping rapidly and soon a whole genome will cost the same as disease-targeted tests.

Cost of the first human genome:
\$2.7 billion

Cost of a genome today: \$9000

Case #1: Whole Exome Sequencing

Autistic
Moderate hearing loss

Child had whole exome sequencing through an autism research study

Incidental finding:
USH2A Tyr4238X/Trp2075X
Causative for Usher syndrome

Case 2: Nonsyndromic Hearing Loss

- Sept 2010: 2 yr old girl born presents to Genetics
- History of congenital bilateral sensorineural hearing loss
- Mild-moderate “cookie-bite” shaped audiogram
- No other complaints

Whole Genome Sequencing Data Analysis

3-5 Million Variants

Genome Comparisons

Frequency

Biallelic

Homozygous Variants

Coding, flanking intronic regions

Truncating, Known pathogenic

Candidate Genes, Expression Patterns, Pathways

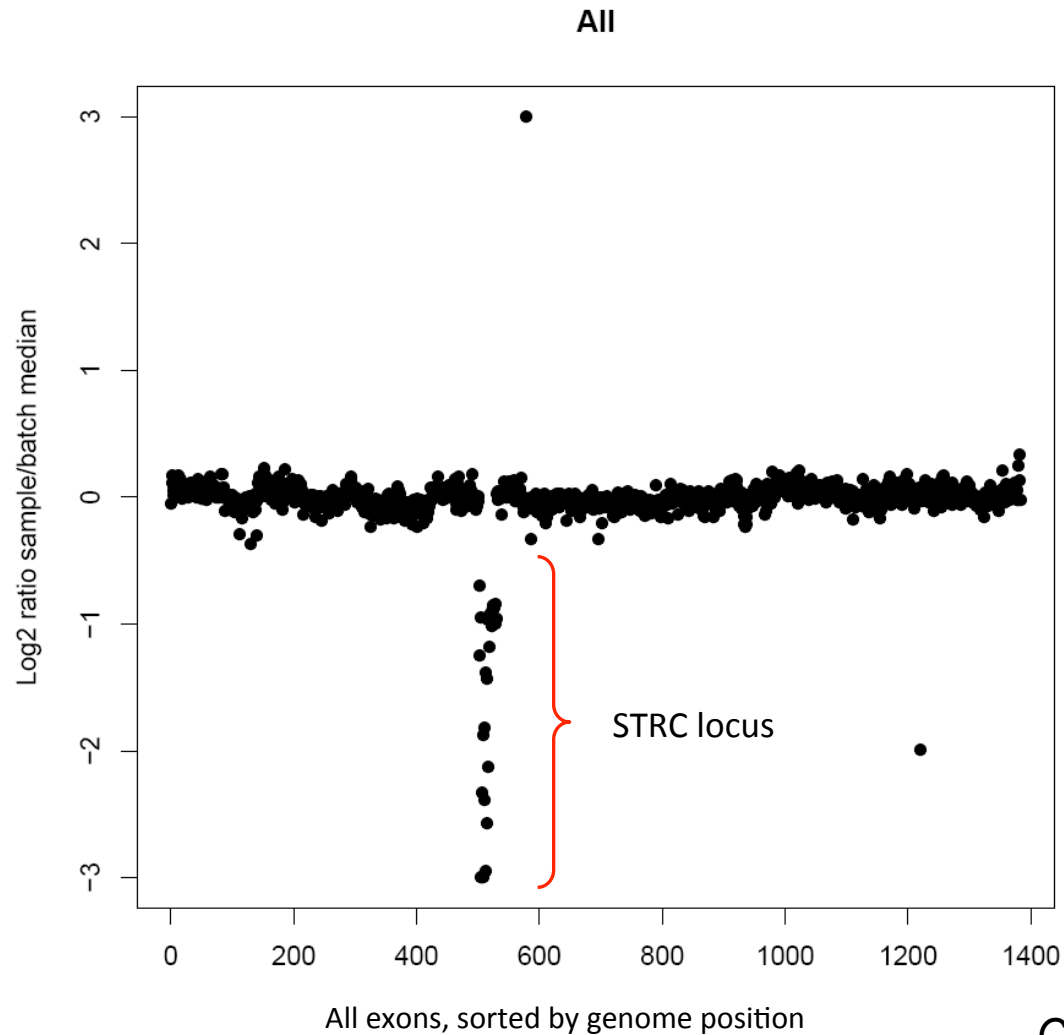

Variants to Be Manually Assessed

0 - 2 Causative Variants

Analyzed WGS Case by OtoGenome Included VisCap Analysis for CNVs

Courtesy of Trevor Pugh

Case 2: Nonsyndromic Hearing Loss

Affected children have a 100,000 bp deletion involving 4 genes.

STRC deletion causes hearing loss
CATSPER deletion causes male infertility

Why is genetic testing useful?

It can detect Usher syndrome before eye disease is apparent.

It can clarify a diagnosis (not all hearing loss with retinal disease is Usher).

The type of mutation may predict disease severity.

Clinical trials may require genetic test confirmation or knowledge of specific gene involved.

Certain therapies may only work on certain types of mutations.

Read-through therapies (e.g. PTC124) only work for nonsense mutations.

It can enable family member testing for carrier status or prenatal/preimplantation testing.
